CRITICALITY AND RISK FOR RECURRENT ACTIVITIES

Abstract

This document describes a pragmatic comprehensive approach to risk management for services provided by IT and GS, integrated with the service catalog, and supported by the CERN service management system.

Prepared by : R. Martens CERN –GS/SMS Reinoud.Martens@cern.ch Checked by : C. Delamare (GS) D. Foster (IT) S. Lettow (DG) M. Moller (IT) T. Pettersson (GS)

1. INTRODUCTION

The aim of a Risk Management process is to support better decision making through a good understanding of risks and their likely impact to the business.

Risk Management involves the identification, selection and adoption of countermeasures justified by the identified risks to assets in terms of their potential impact upon services if failure occurs, and the reduction of those risks to an acceptable level.

During a review of CERN services following an ISO20k approach, we found that we are weak in many areas related to Risk Management:

- Business Continuity and Availability
 - \circ $\;$ No structured approach to risks analysis.
 - In general no business continuity plans (no prioritization in case of problems).
 - Lack of tests when a recovery possibility exists.
 - No measurement of end user availability.
 - Major Incidents handling and reporting.
 - Major incidents managed in ad-hoc improvisation/crisis mode.
- Security
 - Lack of awareness of the issues.
 - Local pockets of excellence (alarms for FB) but no application level security policy yet.
 - Data security policy in its infancy → no clear guidance.

If we want to tackle these issues, we need for a start have a clear idea on

- the criticality of the services we are responsible for (potential impact of service outage),
- the threats (with associated likelihoods) that we can be confronted with, and
- the vulnerabilities of the services to the threats

This document outlines a proposed light weight risk assessment framework that can be implemented and supported as part of the CERN Service Management System.

Page 5 of 16

2. HOW

There are two Phases to the process

- Risk Analysis Understanding the Risks
- Risk Management Managing the Risks in the "live" environment

Literature shows models that can become exceedingly complex as vulnerabilities are assessed before and after mitigating measures are taken. We suggest simplifying the model to a minimum, by applying a **three step approach**, and incorporating mitigating factors into the vulnerability score.

- Score each (Customer) Service with regard to its Criticality (or potential Impact) to CERN. Compute the Criticality of Functions on which the service relies.
- 2. List Threats and score their Likelihood of occurring
- 3. Finally assess a Vulnerability score (taking into account existing mitigating factors) on the intersection of a Function and Threat leading to the automatically calculation of the Risk

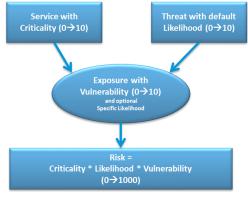

From this value we can understand whether further Risk Mitigation is required and we can take action - the **Risk Management** Phase.

Note: in comparison with other literature:

Risk is often defined as Probability times Impact. (Risk=Probability*Impact) The Criticality of a service is the Impact of the service not being available. (Criticality=Impact) Probability is here broken down into

- A Threat with a Likelihood and
- An Exposure with a Vulnerability

This greatly simplifies the risk assessment (**Probability=Threat*Vulnerability**) as one can think of the threat and the vulnerability separately.

2.1 SERVICES AND CRITICALITY

Below we propose criticality classification guidelines. The "DG scale" is present for 'backward compatibility'; this was the classification proposed some years ago.

Criticality and Impact reflect the same notion and can be interchanged for the purpose of this document.

The safety risk column was added after feedback from various group leaders demanding not only number of people and cost factors should be considered in the classification but safety aspects are also taken into account.

Criticality (impact if we 'loose' the service)					
		Factor	DG scale	Criteria to help in the classification of criticality	Safety Risk
	Nil	1	1	very few people affected; people can work on 'other' activities; workaround exists; cost < 1KCHF; safety is not affected; only visible in small contained area; no reputation issue	Nil / Very
Minor	Hardly visible	2	1	several people affected; cost <5KCHF; safety is not affected; not visible outside CERN; no reputation issue	Limited
	Very limited	3	1	small group of people affected; cost <10KCHF; safety is not affected; not visible outside CERN; no reputation issue	
	Limited	4	1	considerable number of people affected (>20); cost <20KCHF; possibly affecting people outside central services; no reputation issue	
Average	Visible	5	1	considerable number of people affected (>50); cost <50KCHF; possibly affecting people outside CERN; CERN reputation possibly slightly affected	Limited
	Significant	6	1	considerable number of people affected (>100); cost <100KCHF; seriously affecting considerable population inside and outside CERN; CERN reputation possibly affected	
Major	Very significant	7	2	considerable number of people affected (>500); cost <400KCHF; seriously affecting very significant population inside and outside CERN; CERN reputation most likely affected	Significant
Major	Important	8	2	large number of people affected (>1000); cost <1MCHF; very seriously affecting large population inside and outside CERN; significant risk to CERN reputation	Significant
Critical	Disastrous	9	3	large number of people affected (>1000); cost <10MCHF; affecting very large population inside and outside CERN; putting survival of CERN at risk; possible serious injuries	Major
Childa	Catastrophic	10	5	large number of people affected (>1000); cost >10MCHF; affecting large population inside and outside CERN; putting survival of CERN at big risk; possible loss of life	inajoi

It must be noted that levels 9 and 10 are outside the scope of the 'service management system' and thus outside the scope of this document. A 'crisis management' project is ongoing at CERN to cover this area.

These guidelines can also be used to assess the impact of incidents.

Criticality applies to business services. The CERN service catalogue contains the relations between business services and 'functions'. Further down we'll explain how the criticality of a function is derived from the criticality of the related services.

2.2 THREATS AND LIKELIHOOD

	d it happens our Prevention)	Factor	Frequency	DG scale
No (once > 10 years)	Impossible	1	Less than once in a lifetime	1
	Almost impossible	2	Once in a lifetime	1
yearsy	Very unlikely	3	More than 25 years	1
	Unlikely	4	Every 25 years	2
Maybe (once in	Little plausible	5	Every 10 years	2
5-10 years)	Plausible	6	Every 5 years	3
	Likely	7	Every 2.5 years	3
Vac (anao k	Very likely	8	Every year	4
Yes (once <	Almost certain	9	Every month	4
year)	Certain	10	Every day	4

Threat and likelihoods can e.g. depend on location (e.g. an Earthquake is more likely in Italy or Japan than in Sweden possibly) or other factors. We considered it useful to define a 'default' likelihood for threats, in order to simplify the risk assessment. Likelihood of an earthquake to CERN is the same for all services at CERN.

The DG scale was again added for reference only.

Below you can find a proposed list of threats and their associated proposed likelihood levels.

It is suggested the values are set once (by voting

of a team of experts), and may be reviewed whenever necessary.

Threat	Nature	Likelyh	Event	On what	By what	Mitigation/Prevention	Frequency	Financial / Image loss
T1	Disaster		Flood, Storm, Earthquake, Fire destroys part of infrastructure, Plane Crash	All assets	Nature / GOD	Backups / Disaster recovery plan	Every 25 years	>100 Million
T2	Confidentiality / Legal / Reputation	6	CERN is legally reponsible (software disseminated) or confidential personnel data is disseminated; Confidential information falls in the wrong hands. CERN infrastructure is used as platform to propagate or launch cyber attacks, or disseminate intellectual property protected material.	Storage media; Network; All data (including physical files); IT infrastructure		Procedures, Physical protection, Encryption	Every 5 years	1M
T3	Inside Attack (Intentional Malicious Acts / Fraud / Hacking)	5	Disgruntled Employee intentionally alters data/files/settings/etc Or steals resources necessary to provide a service. An attack from 'inside'.	All assets	(ex) internals	Guards, Physical protection, Special monitoring	Every 10 years	?
T4	Terrorist Attack	1	Physical sabotage, bomb, gas, etc	All assets		Guards, Physical protection	Less than once in a lifetime	>100 Million
T5	External Attack (Hacking, Computer Virusses)	6	Sql Injection ; Buffer overflows, etc cause File corruption	Desktop and servers	(ex) internals	Firewall; AntiVirus; Enforced Procedures (for password policy, etc)	Every 5 years	
T6	Material Failure / Loss of Tool / Function / Data	8	Wrong manipulation; Software bug; Material Failure (CPU/Disk/Network/Power/Machine failure; but also a falling tree, a collapsing roof, heating or airconditioning stops due to lack of maintenance etc)	All assets	Power Spikes; Old Age; Weather (Cold/Hot/Wind/Rain/Sn ow)	Redundancy, Preventive Maintenance, Backups	Every year	?
T7	Single point of failure / No plan B / Strike		One person having essential knowledge is absent; one critical piece of equipment has breaks without spare; You can't obtain service from elsewhere on short notice; Support teams stop working	Support or Service	Illness, personnel turnover, component not produced anymore; Bad Contract/CERN Staff Relations	Redundancy	Every 5 years	

Common Threat-Sources

- Natural Threats—Floods, earthquakes, tornadoes, landslides, avalanches, electrical storms, and other such events.
- Human Threats—Events that are either enabled by or caused by human beings, such as unintentional acts (inadvertent data entry) or deliberate actions (network based attacks, malicious software upload, unauthorized access to confidential information).
- Environmental Threats—Long-term power failure, pollution, chemicals, liquid leakage.

Page 8 of 16

2.3 VULNERABILITY

Vulnerability is the level to which an Asset (Service/Function) is exposed to a Threat. As mentioned earlier if a certain region in Italy is exposed to an earthquake with a certain likelihood (say once every 5 years), certain buildings (assets) are possibly designed and build in such a way that their 'vulnerability' to this threat is less than for other buildings. This 'vulnerability' is expressed on a scale of 1 to 10 following these proposed criteria.

Vulnerability of an asset to a threat (after mitigation); the chance a threat if it happens 'breaks' the asset?						
	Impossibly	1				
Not	Improbably	2				
	Unlikely	3				
	With difficulty	4				
	Possibly	5				
Maybe	Likely	6				
	Probably	7				
	Quite easily	8				
Yes	Easily	9				
	Immediately	10				

The vulnerability value incorporates the mitigating measures already taken to reduce the 'exposure'. E.g. if a house has been reinforced to withstand earthquakes its vulnerability will be lower than a house without this reinforcement.

Page 9 of 16

2.4 RISK

Risk is now a simple multiplication of Criticality, Likelihood, and Vulnerability.

Once the result known, the risk can be classified in so called risk classes. Depending on the risk class, mitigating measures might need to be implemented to reduce the exposure.

Risk Class	Threshold	
I	300	Intolerable risk
II	200	Undesirable risk, and tolerable only if risk reduction is impracticable or if the costs are grossly disproportionate to the improvement gained
III	100	Tolerable risk if the cost of risk reduction would exceed the improvement gained
IV		Negligible risk

The following page shows a prototype of what the result of such a risk assessment could look like. On this spread sheet one can set the thresholds for risk classes, and obviously all other parameters mentioned in this document.

3. FUNCTIONS AND SERVICES

Criticality is defined on business service level, and it represents the 'business impact'; the 'what' view.

To assess the exposure to a threat we need to understand the implementation details (the 'how' view, or function view).

The service-catalogue brings the What and How worlds together.

The service catalogue exposes the relationship between functions (e.g. EDH) and services (e.g. Training Application Support). These relationships have an 'importance' that can be A, B or C. A means the service completely relies on the function, if the function stops, the service is severely impacted (e.g. CTA is the training application, one can see that without CTA, the Training Application Support function is heavily impacted). C means there is a dependency, but the service can run for a while without the function being available (e.g. without Qualiac the training sessions cannot be billed to the participants, so there is an impact; however the training service can easily run without this billing feature for some time).

As mentioned, criticality is set on the business service level. The assessment of vulnerability to threats is performed on the function level (one

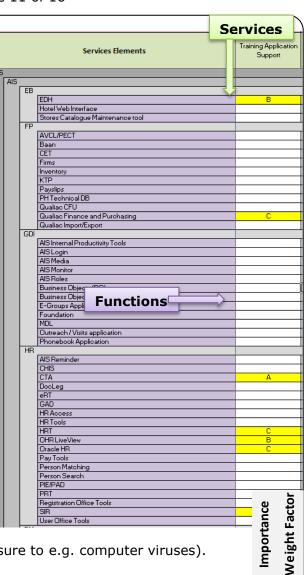

needs knowledge on how things work to assess exposure to e.g. computer viruses).

Thus: once the criticality of services is determined, the criticality of the functions is computed as the maximum of the criticality of related services times a weight factor depending on the importance of their relationship (as shown to the right).

Function.Criticality = Max (For all related services) (Service.Criticality * Relation.Weight_Factor)

Once the Risks are established for the Functions, one can assess the exposure of a Service to a Threat by inspecting the related functions and applying the same weighting principle the other way around: Service.Risk_(For a Threat) = Max (For all related Functions and a Threat) (Service.Criticality * Threat.Likelihood * Vulnerability * Relation.Weight_Factor)

In fact we use the Service Criticality instead of the Function Criticality in the formula and weight the vulnerability with the weight factor of the importance of the function for the service.

4. SUGGESTED NEXT STEPS

The various notions presented in this document are now supported by the service management system.

The concepts were validated by GS and IT management.

The business service criticality should be defined by the customer, however in absence of a customer we propose that this assessment is done by peers, and validated by major stakeholders.

The threat list can also be validated by a team of people that could determine the likelihood values through a 'voting' process.

The vulnerability values should be proposed by the 'specialists' of each function as these people know the implementation details necessary to make the correct assessment. The values should be vetted by a small group of experts in order to guarantee coherency across the board.

5. CONCLUSION

This light weight risk assessment would constitute a significant improvement to the maturity of CERN's service management system, although it's just a first step to improve the situation in the areas of business continuity and availability management.

An agreed classification of Criticality (Impact) is also necessary to implement major incident handling.

APPENDIX 1: IMPLEMENTATION

Practical implementation in Service-Now of the concepts presented in this paper.

Service-now contains a "Governance, Risk and Compliance" (or GRC) module. This module can be used out of the box, with very minor changes

The Criticality of a Functional and Service are stored as 'Business Criticality' attributes of a service element (Read/Write) and functional element (Read only computed attribute).

The Threats are implemented as "Risk Criteria's" (of type Likelihood) with a weight. Adjusting this weight will impact all the associated risks.

Vulnerabilities were implemented as "Risk Criteria's" (of type Significance) with a weight.

	Significance	Impossible	1

Risks are now defined as the combination of a threat and a functional service. In the example below 'Strike' for 'Stores Urgency Counter'. The Vulnerability (Significance) is the only attribute that needs to be set on this level. The Risk and Risk Class are automatically calculated.

€ ▼Risk			Update Save Delete 🔋 🕆 🦊
Risk ID:	RISK0006840	Risk name:	Strike for Stores Urgency Counter
Functional Element:	Stores Urgency Counter 🔍 🐻	Risk:	224
Business criticality:	4 - Limitted 🔻	Risk Class:	2
Threat:	Strike 🔻 🐻		
Vulnerability:	Quite easily -		
Description:			⊟ ±

As stores urgency counter is staffed by the QUIRCO contract, which is a company known for it's bad relationships with its employees, the risk of strike is quite high.
